Abstract

A generalized filter construction is used to build an example of a non-MRA normalized tight frame wavelet for dilation by 2 in $L^2(\mathbb{R})$. This example has the same multiplicity function as the Journé wavelet, yet has a C^∞ Fourier transform and can be made to be C^r for any fixed positive integer r .

Keywords: Wavelet; Multiresolution analysis; Frame

1 Introduction

A central problem in the history of wavelet theory has been the search for smooth well-localized functions whose dilates and translates can be used to obtain all

members of a specified function space. We will use here the simplest definition of an orthonormal wavelet, by taking our context to be dilation by 2 in $L^2(\mathbb{R})$:

Definition 1. $\psi \in L^2(\mathbb{R})$ is an **orthonormal wavelet** if $\{\psi_{j,k} \equiv \sqrt{2}^j \psi(2^j x - k)\}_{j,k \in \mathbb{Z}}$ form an orthonormal basis for $L^2(\mathbb{R})$.

Many of the techniques and results used in this paper apply in much wider contexts, to dilation by an expansive matrix in $L^2(\mathbb{R}^n)$, and to allow for multiple wavelets. However, for the purposes of creating the example that is the main thrust of this paper, this more restrictive context will suffice.

The earliest example of an orthonormal wavelet was given by A. Haar in 1910 [18]. Here the wavelet is defined in terms of characteristic functions of bounded sets,

$$\psi = \chi_{[0, \frac{1}{2})} - \chi_{[\frac{1}{2}, 1)},$$

and thus is well-localized but not at all smooth. Another famous classical example, the Shannon wavelet, has Fourier transform of the wavelet equal to a characteristic function of a bounded set,

$$\widehat{\psi} = \chi_{[-1, -\frac{1}{2}) \cup [\frac{1}{2}, 1)},$$

and thus has the opposite problem of being smooth but not well-localized. In 1988, Ingrid Daubechies [17] gave a construction technique for orthonormal wavelets for dilation by 2 in $L^2(\mathbb{R})$ that are both smooth and well-localized. She described how to build, for any integer $r \geq 0$, a wavelet that is C^r and has compact support. It can be shown that no wavelet can be both C^∞ and have compact support (see e.g. [20]).

Daubechies' construction technique used filters in a multiresolution structure called an MRA. Most classical wavelets are associated with such a structure. J.L. Journé gave the first known example of a wavelet that can not have an associated MRA (see [22]). Journé's wavelet, like the Shannon wavelet, is a *wavelet set* wavelet. That is, its Fourier transform is a characteristic function. Since the announcement of the Journé wavelet, many other non-MRA wavelets have appeared in the literature (see e.g. [15], [8] [6]), most of them also wavelet set wavelets. These wavelets are smooth but not well-localized. In fact, it can be shown that every orthonormal wavelet ψ such that $|\widehat{\psi}|$ is continuous and $|\widehat{\psi}(\xi)| = O(|\xi|^{-\frac{1}{2}-\epsilon})$ at ∞ for some $\epsilon > 0$ must be an MRA wavelet (see [20]). Thus, in the quest to find wavelets that are both well-localized and smooth, non-MRA wavelets would seem to be not very useful. However, if we expand our definition of wavelet slightly, the situation changes.

Definition 2. The set of functions $\{\eta_j\}$ is a frame for $L^2(\mathbb{R})$ if there exist constants A and B such that for each $f \in L^2(\mathbb{R})$ we have $A\|f\|^2 \leq \sum_j |\langle f | \eta_j \rangle|^2 \leq B\|f\|^2$. The set $\{\eta_j\}$ is a normalized tight frame or Parseval frame if $A = B = 1$.

Definition 3. $\psi \in L^2(\mathbb{R})$ is a (normalized tight) frame wavelet or a Parseval frame wavelet for dilation by 2 if $\{\psi_{j,l} \equiv \sqrt{2}^j \psi(2^j x - l)\}$ form a normalized tight frame for $L^2(\mathbb{R})$.

Note that a normalized tight frame can exhibit redundancy, and therefore need not be a basis. Indeed, it can include 0 as one of its elements. However, a normalized tight frame $\{\eta_j\}$ does have the property that every $f \in L^2$ can be recaptured from its coefficients, $f = \sum \langle f, \eta_j \rangle \eta_j$. (See, e.g. [20]). Thus replacing orthonormal wavelets by frame wavelets does not give up the essential property of determining all functions in L^2 in terms of translates and dilates of the wavelet.

Our main goal in this paper is to produce an example of a non-MRA normalized tight frame wavelet for dilation by 2 in $L^2(\mathbb{R})$ which is both well-localized and smooth, in the sense that $\psi \in C^r$ (for any fixed positive integer r) and $\hat{\psi} \in C^\infty$. The existence of such a wavelet is somewhat surprising in view of the result mentioned above for orthonormal wavelets. While several researchers have produced examples of frame wavelets that exhibit smoothness and good localization properties (See e.g. [1]), the example in this paper stands out in its relationship to a non-MRA multiresolution structure with a known multiplicity function. For such a non-MRA wavelet, the multiresolution structure will be replaced by a generalized multi-resolution structure called a GMRA, defined in [6], which we review in Section 2 of this paper. We note that similar generalizations of multi-resolution structures have also been defined in [9] and [19].

The Fourier transform is an essential tool in analyzing wavelets; we will use it and a generalization in the GMRA context to define filters used in wavelet construction. We take as the definition of the Fourier transform,

$$\hat{f}(x) = \int_{\mathbb{R}} f(t) e^{-2\pi i x t} dt.$$

Note that on $\widehat{L^2}(\mathbb{R})$, translation by n becomes multiplication by $e^{2\pi i n x}$, and dilation becomes $\hat{\delta}f(x) = \frac{1}{\sqrt{2}}f(\frac{x}{2})$. We review the filter construction process and its generalization in Section 3 of this paper. In Section 4 we build our main example.

2 Generalized multi-resolution analyses

As mentioned in the introduction, most classical wavelets have an associated multi-resolution structure of the following type, first defined by S. Mallat [22]:

Definition 4. A Multiresolution Analysis (MRA) in $L^2(\mathbb{R})$ is a collection of closed subspaces V_j that have the following properties:

1. $V_j \subset V_{j+1}$
2. $V_{j+1} = \{\delta(f) \equiv \sqrt{2}f(2x)\}_{f \in V_j}$
3. $\cup V_j$ is dense in $L^2(\mathbb{R})$ and $\cap V_j = \{0\}$
4. V_0 has a scaling function ϕ whose translates form an orthonormal basis for V_0

However, the Journé wavelet (see [22]),

$$\widehat{\psi} = \chi_{[-\frac{16}{7}, -2) \cup [-\frac{1}{2}, -\frac{2}{7}) \cup [\frac{2}{7}, \frac{1}{2}] \cup [2, \frac{16}{7})}.$$

has no associated MRA. This can be shown using the dimension function,

$$D(x) \equiv \sum_{k \in \mathbb{Z}} \sum_{j=1}^{\infty} |\widehat{\psi}(2^j(x+k))|^2, \quad (1)$$

first introduced by P. Auscher [2]. Because an MRA requires the existence of a scaling function, it turns out that a wavelet has an associated MRA if and only if the dimension function is identically equal to 1 (see e.g. [20]). By removing the scaling function condition, we are able to associate a multiresolution structure with the Journé wavelet. More generally, given any orthonormal wavelet $\psi \in L^2(\mathbb{R})$, the subspaces $\{V_j\}$ defined by V_j = the closed linear span of $\{\psi_{l,k}\}_{l < j}$, do determine a *generalized* multiresolution structure, according to the definition below [6]:

Definition 5. A Generalized Multiresolution Analysis (GMRA) is a collection of closed subspaces $\{V_j\}_{j \in \mathbb{Z}}$ of $L^2(\mathbb{R})$ such that:

1. $V_j \subset V_{j+1}$
2. $V_{j+1} = \{\delta(f) \equiv \sqrt{2}f(2x)\}_{f \in V_j}$
3. $\cup V_j$ dense in $L^2(\mathbb{R})$ and $\cap V_j = \{0\}$
4. V_0 is invariant under translation.

The definitions of MRA and GMRA differ only in condition (4): An MRA requires that V_0 has a scaling function ϕ such that translates of ϕ form an orthonormal basis for V_0 , while a GMRA requires only that V_0 be invariant under translation by the integers. In spite of this difference, it is shown in [6] that a GMRA has almost as much structure as an MRA. Translation is a unitary representation of $\mathbb{Z}$ on V_0 , and thus is completely determined by a multiplicity function $m : [-\frac{1}{2}, \frac{1}{2}) \mapsto \{0, 1, 2, \dots, \infty\}$ describing how many times each character occurs as a subrepresentation. The multiplicity function has been shown [25] to be equal to the dimension function defined in Eq. (1). By writing $V_1 = V_0 \oplus W_0$, representation theory can be used (see [6]) to show that the GMRA has an associated orthonormal wavelet if and only if the multiplicity function satisfies a *consistency equation*:

$$m(x) + 1 = m\left(\frac{x}{2}\right) + m\left(\frac{x+1}{2}\right).$$

A GMRA is an MRA iff $m \equiv 1$, and Journé's famous non-MRA wavelet example has

$$m(x) = \begin{cases} 2 & x \in [-\frac{1}{7}, \frac{1}{7}) \\ 1 & x \in \pm[\frac{1}{7}, \frac{2}{7}) \cup \pm[\frac{3}{7}, \frac{1}{2}) \\ 0 & \text{otherwise} \end{cases}$$

In every GMRA, there is a unitary equivalence between translation on V_0 and multiplication by exponentials on $\oplus L^2(S_j)$, where $S_j = \{x : m(x) \geq j\}$. This unitary equivalence plays a role here similar to that of the Fourier transform in the classical MRA case. It ensures that a GMRA whose multiplicity function is finite a.e. has *generalized scaling functions*, $\phi_1, \phi_2, \dots$ such that $\{\phi_i(x-l)\}$ form a normalized tight frame for V_0 . If m is bounded, with maximum value c , then c generalized scaling functions are required. If the GMRA is associated with a wavelet set wavelet, these functions can be chosen of the form $\widehat{\phi}_i = \chi_{E_i}$, where χ_{E_i} is the characteristic function of the set E_i , chosen to be congruent mod 1 to S_i , and so that $\cup E_i \subset 2(\cup E_i)$. (For more details see Theorem 3.5 of [7].) For example, the Journé wavelet has generalized scaling functions $\widehat{\phi}_1 = \chi_{[-\frac{2}{7}, \frac{2}{7}) \cup \pm[\frac{1}{2}, \frac{4}{7})}$ and $\widehat{\phi}_2 = \chi_{\pm[1, \frac{8}{7})}$

3 Filter constructions

We begin by recalling the classical filter construction developed by Mallat [22] and Meyer [23], and used by Daubechies [16] to build C^r wavelets with compact support. Thus, suppose we have a single wavelet ψ for dilation by 2 in $L^2(\mathbb{R})$, with an associated MRA, and so a scaling function ϕ whose translates form an orthonormal basis for V_0 .

Because $\widehat{\phi}$ and $\widehat{\psi}$ are in $\widehat{V}_1$, we can write $\widehat{\phi}$ and $\widehat{\psi}$ in terms of exponentials times the dilate of $\widehat{\phi}$. That is, there must exist periodic functions (with period 1) h and g such that

$$\widehat{\phi}(x) = \frac{1}{\sqrt{2}} h\left(\frac{x}{2}\right) \widehat{\phi}\left(\frac{x}{2}\right) \quad (2)$$

and

$$\widehat{\psi}(x) = \frac{1}{\sqrt{2}} g\left(\frac{x}{2}\right) \widehat{\phi}\left(\frac{x}{2}\right). \quad (3)$$

The functions h and g are called **low and high pass filters**. The roots of this name can be seen by noting that for the Shannon wavelet, $h = \sqrt{2}\chi_{[-\frac{1}{4}, \frac{1}{4})}$ and $g = \sqrt{2}\chi_{[-\frac{1}{2}, -\frac{1}{4}) \cup [\frac{1}{4}, \frac{1}{2})}$ do indeed act by filtering out all but low (for h) or high (for g) frequencies. Because of the orthonormality conditions satisfied by translates of ϕ and ψ , all filters defined by Eqs.(2) and (3) must satisfy orthonormality-like conditions:

$$|h(x)|^2 + |h(x + \frac{1}{2})|^2 = 2 \quad (4)$$

$$|g(x)|^2 + |g(x + \frac{1}{2})|^2 = 2 \quad (5)$$

and

$$h(x)\overline{g(x)} + h(x + \frac{1}{2})\overline{g(x + \frac{1}{2})} = 0. \quad (6)$$

The classical filter techniques for building wavelets reverse this process of finding filters from wavelets. First note that if h is any periodic function that satisfies Eq.(4), the function

$$g(x) = e^{2\pi i x} \overline{h(x + \frac{1}{2})}, \quad (7)$$

and h together satisfy all three orthonormality conditions (4),(5) and (6). (Other choices for g are possible.) The following classical theorem gives conditions under which the Fourier transform of a scaling function $\hat{\phi}$ can then be built by iterating Eq.(2), so that the Fourier transform of a wavelet, $\hat{\psi}$, can be defined using Eq.(3).

Theorem 1. *Let h and g be C^1 functions that satisfy the orthonormality conditions (4), (5), and (6). Suppose, in addition, that h is nonvanishing on $[-\frac{1}{4}, \frac{1}{4}]$, and $|h(0)| = \sqrt{2}$. Then:*

$$\hat{\phi}(x) = \prod_{j=1}^{\infty} \frac{1}{\sqrt{2}} h(2^{-j}x)$$

is a scaling function for an MRA, and

$$\hat{\psi}(x) = \frac{1}{\sqrt{2}} g\left(\frac{x}{2}\right) \hat{\phi}\left(\frac{x}{2}\right).$$

is an orthonormal wavelet.

A good introductory description of these constructions appears in [24].

The theorem's requirements that h satisfy $|h(0)| = \sqrt{2}$ and that h be in C^1 are natural restrictions in order to make the infinite product converge. The condition that h is nonvanishing on $[-\frac{1}{4}, \frac{1}{4}]$ appears less natural; it is used in the proof to ensure L^2 convergence of the infinite product and thus the orthonormality of the translates of ϕ . A famous example due to A. Cohen [12] showed that this nonvanishing condition cannot be entirely removed, as its removal can lead to functions ϕ and ψ whose translates are not orthonormal. Cohen took $h = \frac{1+e^{-6\pi i x}}{\sqrt{2}}$, which resulted in a stretched out version of the Haar scaling function and wavelet, $\phi = \frac{1}{3}\chi_{[0,3)}$ and $\psi = \frac{1}{3}(\chi_{[0,\frac{3}{2})} - \chi_{[\frac{3}{2},3)})$. Cohen's ψ is not a wavelet, since its translates are not orthonormal. However, the classical Theorem 1 can be extended to accommodate this and similar examples if we allow (normalized tight) frame wavelets. The following generalization of Theorem 1 was first proven by Lawton in [21], with a generalized form appearing later in Bratteli and Jorgensen's book [11]:

Theorem 2. *Suppose h, g are periodic Lipschitz continuous function in $L^2(\mathbb{R})$, which satisfy $|h(0)| = \sqrt{2}$ and the filter equations (4), (5) and (6). Then the construction $\hat{\phi}(x) = \prod_{j=1}^{\infty} \frac{1}{\sqrt{2}} h(2^{-j}x)$ produces an L^2 function ϕ (whose translates are not necessarily orthogonal), and the function $\hat{\psi}(x) = \frac{1}{\sqrt{2}} g\left(\frac{x}{2}\right) \hat{\phi}\left(\frac{x}{2}\right)$ is a (normalized tight) frame wavelet for dilation by 2 in $L^2(\mathbb{R})$.*

The classical filter construction that was used in both the original theorem and this extension was generalized to GMRA's in [4]. Just as in the classical case, it is natural to begin by building filters from wavelets, and then determine conditions under which the process can be reversed. Accordingly, suppose first that ψ is a non-MRA orthonormal wavelet for dilation by 2 in $L^2(\mathbb{R})$ whose multiplicity function is bounded by c . We have seen in Section 2 that there then exist generalized scaling functions $\phi_1, \dots, \phi_c$. Since $\widehat{\phi}$ and $\widehat{\psi}$ are in $\widehat{V}_1$, we can show (see [4]) there exist periodic functions $h_{i,j}$ and g_j , supported on the periodization of S_j , such that

$$\widehat{\phi}_i(x) = \frac{1}{\sqrt{2}} \sum_{j=1}^c h_{i,j}\left(\frac{x}{2}\right) \widehat{\phi}_j\left(\frac{x}{2}\right) \quad (8)$$

and

$$\widehat{\psi}(x) = \frac{1}{\sqrt{2}} \sum_{j=1}^c g_j\left(\frac{x}{2}\right) \widehat{\phi}_j\left(\frac{x}{2}\right). \quad (9)$$

These *generalized filters* g_j and $h_{i,j}$ satisfy orthonormality-like conditions that are generalizations of the classical conditions (4), (5) and (6):

$$\sum_{j=1}^c h_{i,j}\left(\frac{x}{2}\right) \overline{h_{k,j}\left(\frac{x}{2}\right)} + h_{i,j}\left(\frac{x+1}{2}\right) \overline{h_{k,j}\left(\frac{x+1}{2}\right)} = 2\delta_{i,k} \chi_{S_i}(x), \quad (10)$$

$$\sum_{j=1}^c |g_j\left(\frac{x}{2}\right)|^2 + |g_j\left(\frac{x+1}{2}\right)|^2 = 2, \quad (11)$$

and

$$\sum_{j=1}^c h_{i,j}\left(\frac{x}{2}\right) \overline{g_j\left(\frac{x}{2}\right)} + h_{i,j}\left(\frac{x+1}{2}\right) \overline{g_j\left(\frac{x+1}{2}\right)} = 0, \quad (12)$$

For example, for the Journé wavelet these filters are defined (see [13]) by:

$$h_{1,1} = \sqrt{2} \chi_{[-\frac{2}{7}, -\frac{1}{4}) \cup (-\frac{1}{7}, \frac{1}{7}) \cup [\frac{1}{4}, \frac{2}{7})}$$

$$h_{1,2} = 0,$$

$$h_{2,1} = \sqrt{2} \chi_{[-\frac{4}{7}, -\frac{1}{2}) \cup [\frac{1}{2}, \frac{4}{7})}$$

$$h_{2,2} = 0$$

$$g_1 = \sqrt{2} \chi_{[-\frac{1}{4}, -\frac{1}{7}) \cup [\frac{1}{7}, \frac{1}{4})}$$

$$g_2 = \sqrt{2} \chi_{[-\frac{1}{7}, \frac{1}{7})}.$$

To use generalized filters to build new wavelets, we reverse this procedure, just as in the classical case. In order to first build filters, we use functions on the disjoint union of the S_j 's whose values are $\sqrt{2}$ times unitary matrices, with different dimensions for different values of x . We need the values of the filters to be $\sqrt{2}$ times unitary matrices in order to satisfy the generalized orthonormality conditions (10), (11), and (12). The matrices of filter values have different dimensions depending on how many of the sets S_j the point x and its preimages are in. Once we have the filters, we build the generalized scaling function using an infinite product of matrices that comes from the iteration of Eq.(8). The wavelet is then produced by Eq.(9). Conditions that make this possible are described in the following generalization (see [5]) of the Lawton theorem :

Theorem 3. *Given a multiplicity function m for a GMRA, suppose $\{h_{i,j}\}$ and $\{g_j\}$ are periodic functions that are supported on the periodization of $S_j = \{x : m(x) \geq j\}$, Lipschitz continuous in a neighborhood of the origin, and that satisfy the three generalized orthonormality conditions (10), (11), and (12). Suppose in addition the $h_{i,j}$ satisfy the generalized lowpass condition $|h_{i,j}(0)| = \sqrt{2}\delta_{(i,1)}\delta_{(j,1)}$. Write H for the matrix $(h_{i,j})$. Then the components of $\prod_{k=1}^{\infty} \frac{1}{\sqrt{2}} H(2^{-k}x)$ converge pointwise to L^2 functions. If we let $\{\widehat{\phi}_i\}_{i=1}^c$ be the first column of this product, then the translates of $\{\phi_i\}$ determine the core subspace V_0 of a GMRA, and*

$$\widehat{\psi}(x) \equiv \frac{1}{\sqrt{2}} g_1\left(\frac{x}{2}\right) \widehat{\phi}_1\left(\frac{x}{2}\right) + g_2\left(\frac{x}{2}\right) \widehat{\phi}_2\left(\frac{x}{2}\right)$$

is the Fourier transform of a normalized tight frame wavelet on $L^2(\mathbb{R})$.

The proof, like that of [11], proceeds by using matrices of values of the filters to define partial isometries that satisfy relations similar to those defining a Cuntz algebra as in [14]. We will use this theorem in the next section to build our main example.

4 The Example

For any fixed positive integer r , we will now use Theorem 3 to build an example of a C^r frame wavelet with C^∞ Fourier transform, whose multiplicity function is that of Journé:

$$m(x) = \begin{cases} 2 & x \in [-\frac{1}{7}, \frac{1}{7}) \\ 1 & x \in \pm[\frac{1}{7}, \frac{3}{7}) \cup \pm[\frac{3}{7}, \frac{1}{2}) \\ 0 & \text{otherwise} \end{cases}$$

To do this, we will first choose low-pass filters that force the functions $\widehat{\phi}_1$ and $\widehat{\phi}_2$ in the infinite matrix product to both be smooth and have rapid decay. We will then define the high-pass filters, and show that the resulting wavelet inherits the properties we seek.

From the equation for m , we see that the sets $S_j = \{x : m(x) \geq j\}$ used in the filter construction are here given by $S_1 = [-\frac{2}{7}, \frac{2}{7}) \cup \pm[\frac{3}{7}, \frac{1}{2})$ and $S_2 = [-\frac{1}{7}, \frac{1}{7})$. We will define the filter functions $h_{i,j}$, $1 \leq i, j \leq 2$ in terms of a classical filter p . Accordingly, with r fixed as above, let p be a periodic (with period 1), real-valued function that satisfies:

1. $p \in C^\infty(\mathbb{R})$
2. $p(x) = p(-x)$
3. $|p(x)|^2 + |p(x + \frac{1}{2})|^2 = 2$
4. $p^{(k)}(x) = 0$ for $x \in [\frac{1}{7}, \frac{3}{14}] \cup [\frac{3}{7}, \frac{1}{2}]$, $k \geq 0$.
5. $|p^{(r+2)}(x)| < 1$ when $|x - \frac{3}{14}| < \frac{1}{112}$ or $|x - \frac{1}{7}| < \frac{1}{112}$

To see that such a function exists, note that it suffices to define $p \in C^\infty([\frac{3}{28}, \frac{1}{4}] \cup [\frac{11}{28}, \frac{1}{2}])$, satisfying conditions (4) and (5), and with $p(\frac{3}{28}) = p(\frac{1}{4}) = p(\frac{11}{28}) = 1$ and $p^{(k)}(\frac{3}{28}) = p^{(k)}(\frac{1}{4}) = p^{(k)}(\frac{11}{28}) = 0$ for $k \geq 1$. We can then define p on $[0, \frac{3}{28}] \cup [\frac{1}{4}, \frac{11}{28}]$ by $p(x) = \sqrt{2 - p(\frac{1}{2} - x)^2}$. We then extend p to $[-\frac{1}{2}, 0]$ using the requirement that p be symmetric, and finally extend p to the whole line using periodicity. Figure 1 below shows a C^1 approximation to p .

Figure 1: A C^1 approximation to p

We now use this function p to build the low-pass filters $\{h_{i,j}\}$:

$$h_{1,1}(x) = \begin{cases} p(x) & x \in [-\frac{2}{7}, \frac{2}{7}) \\ 0 & \text{otherwise} \end{cases} \quad (13)$$

$$h_{1,2}(x) = \begin{cases} p(x + \frac{1}{2}) & x \in [-\frac{1}{7}, \frac{1}{7}) \\ 0 & \text{otherwise} \end{cases} \quad (14)$$

$$h_{2,1}(x) = \begin{cases} \sqrt{2} & x \in \pm[\frac{3}{7}, \frac{1}{2}) \\ 0 & \text{otherwise} \end{cases} \quad (15)$$

$$h_{2,2}(x) = 0 \quad (16)$$

Figures 2 through 4 show C^1 approximations to the three nonzero low-pass filters.

Figure 2: An approximation to $h_{1,1}$

It is easy to check that these functions satisfy the filter equation (10). For example, to check that

$$|h_{1,1}(\frac{x}{2})|^2 + |h_{1,2}(\frac{x}{2})|^2 + |h_{1,1}(\frac{x+1}{2})|^2 + |h_{1,2}(\frac{x+1}{2})|^2 = 2\chi_{[-\frac{2}{7}, \frac{2}{7}] \cup \pm[\frac{3}{7}, \frac{1}{2}]}(x),$$

we note that the left hand side gives

$$\begin{cases} |p(\frac{x}{2})|^2 + |p(\frac{x+1}{2})|^2 + 0 + 0 & = 2 \text{ for } x \in [-\frac{2}{7}, \frac{2}{7}] \\ |p(\frac{x}{2})|^2 + 0 + 0 + 0 & = 0 \text{ for } x \in \pm[\frac{2}{7}, \frac{3}{7}] \\ |p(\frac{x}{2})|^2 + 0 + |p(\frac{x+1}{2})|^2 + 0 & = 2 \text{ for } x \in \pm[\frac{3}{7}, \frac{1}{2}] \end{cases}$$

The other cases of (10) follow similarly from the definitions of the $h_{i,j}$ and the properties of p . It is also easy to check that the $\{h_{i,j}\}$ have proper support and satisfy the low-pass condition, $h_{1,1}(0) = \sqrt{2}$ and $h_{i,j}(0) = 0$ for $(i,j) \neq (0,0)$.

As in Theorem 3, we will define the functions $\widehat{\phi}_1$ and $\widehat{\phi}_2$ (and thus the GMRA that they determine) in terms of the low-pass filter $\{h_{i,j}\}$. First we will need the following technical lemma:

Figure 3: An approximation to $h_{1,2}$

Lemma 1. *For every integer $n \geq 1$, the $(3n)^{th}$ partial product of the filter matrices $\prod_{j=1}^{3n} \frac{1}{\sqrt{2}} \begin{pmatrix} h_{1,1}(\frac{x}{2^j}) & h_{1,2}(\frac{x}{2^j}) \\ h_{2,1}(\frac{x}{2^j}) & 0 \end{pmatrix}$ is a lower triangular matrix $\begin{pmatrix} a_n(x) & 0 \\ c_n(x) & d_n(x) \end{pmatrix}$ whose nonzero components have the following support:*

$$\text{support}(a_n) = \left(8^n \mathbb{Z} + \left(\left[-\frac{2}{7}, \frac{2}{7} \right] \cup \pm \left[\frac{3}{7}, \frac{4}{7} \right] \bigcup \bigcup_{k=0}^{n-2} A_k \bigcup \bigcup_{k=0}^{n-1} B_k \right) \right)$$

$$\bigcup (4 \cdot 8^{n-1} \mathbb{Z} + A_{n-1})$$

$$\text{support}(c_n) = 8^n \mathbb{Z} + \bigcup_{k=0}^{n-1} C_k$$

$$\text{support}(d_n) = 8^n \mathbb{Z} + C_{n-1}$$

where

$$A_k = \bigcup_{\{a_j\} \in \{1, -1\}^{k+1}} \sum_{j=0}^k 2a_j 8^j + \pm \left[\frac{1}{7}, \frac{2}{7} \right],$$

$$B_k = \bigcup_{\{a_j\} \in \{1, -1\}^{k+1}} \sum_{j=0}^k 4a_j 8^j + \pm \left[\frac{3}{7}, \frac{4}{7} \right],$$

$$\text{and } C_k = \bigcup_{\{a_j\} \in \{1, -1\}^{k+1}} \sum_{j=0}^k a_j 8^j + \left[-\frac{1}{7}, \frac{1}{7} \right].$$

Figure 4: An approximation to $h_{2,1}$

Proof. The proof is by induction on n . Both the $n = 1$ case and the induction step follow directly from the observation that

$$\prod_{j=1}^3 \begin{pmatrix} h_{1,1}(\frac{x}{2^j}) & h_{1,2}(\frac{x}{2^j}) \\ h_{2,1}(\frac{x}{2^j}) & 0 \end{pmatrix} = \begin{pmatrix} t_{1,1}(x) & 0 \\ t_{2,1}(x) & t_{2,2}(x) \end{pmatrix}$$

where

$$t_{1,1}(x) = h_{1,1}(\frac{x}{2})h_{1,1}(\frac{x}{4})h_{1,1}(\frac{x}{8}) + h_{1,2}(\frac{x}{2})h_{2,1}(\frac{x}{4})h_{1,1}(\frac{x}{8}) + h_{1,1}(\frac{x}{2})h_{1,2}(\frac{x}{4})h_{2,1}(\frac{x}{8})$$

has support

$$8\mathbb{Z} + ([-\frac{2}{7}, \frac{2}{7}] \cup \pm[\frac{3}{7}, \frac{4}{7}]) \bigcup 4\mathbb{Z} + 2 \pm [\frac{1}{7}, \frac{2}{7}] \bigcup 8\mathbb{Z} + 4 \pm [\frac{3}{7}, \frac{4}{7}],$$

and both

$$t_{2,1}(x) = h_{2,1}(\frac{x}{2})h_{1,1}(\frac{x}{4})h_{1,1}(\frac{x}{8})$$

and

$$t_{2,2}(x) = h_{2,1}(\frac{x}{2})h_{1,1}(\frac{x}{4})h_{1,2}(\frac{x}{8})$$

have support

$$8\mathbb{Z} \pm [\frac{6}{7}, \frac{8}{7}].$$

□

Remark 1. Since [5] shows that the infinite product of filter matrices,

$$\prod_{j=1}^{\infty} \frac{1}{\sqrt{2}} \begin{pmatrix} h_{1,1}(\frac{x}{2^j}) & h_{1,2}(\frac{x}{2^j}) \\ h_{2,1}(\frac{x}{2^j}) & 0 \end{pmatrix}$$

converges pointwise, Lemma 1 gives the support of the elements of this matrix. In particular, the support of the upper left element (which will be used to define $\widehat{\phi}_1$) is $[-\frac{2}{7}, \frac{2}{7}] \cup \pm[\frac{3}{7}, \frac{4}{7}] \cup \bigcup_{k=0}^{\infty} A_k \cup \bigcup_{k=0}^{\infty} B_k$, and the support of the lower left element (which will be used to define $\widehat{\phi}_2$) is $\bigcup_{k=0}^{\infty} C_k$. Note that these supports are disjoint.

We will use this result to characterize the GMRA for the wavelet we will build.

Proposition 1. The functions $\widehat{\phi}_1$ and $\widehat{\phi}_2$ given by the upper left and lower left elements of the infinite product matrix $\prod_{j=1}^{\infty} \frac{1}{\sqrt{2}} \begin{pmatrix} h_{1,1}(\frac{x}{2^j}) & h_{1,2}(\frac{x}{2^j}) \\ h_{2,1}(\frac{x}{2^j}) & 0 \end{pmatrix}$ determine a GMRA with multiplicity function the same as the Journé wavelet.

Proof. Define $\widehat{V}_0$ to be the closed linear span of exponentials times $\widehat{\phi}_1$ and $\widehat{\phi}_2$, or in other words, define V_0 to be the closed linear span of translates of ϕ_1 and ϕ_2 . A GMRA can be built from this core subspace V_0 in a natural way, by letting $V_j = \{\delta^j(f) \equiv \sqrt{2^j} f(2^j x)\}_{f \in V_0}$. By [5], the resulting structure does satisfy all the components of Definition 5. To find the multiplicity function associated with this GMRA, we note first that Lemma 1 shows that the supports of $\widehat{\phi}_1$ and $\widehat{\phi}_2$ are disjoint, so that the multiplicity function is the sum of the multiplicity functions determined by the two functions separately. By [3], the multiplicity function associated with $\widehat{\phi}_j$ is the characteristic function of the support of the periodic function $\text{Per } \phi_j(x) = \sum_{l \in \mathbb{Z}} |\widehat{\phi}_j(x + l)|^2$. From Lemma 1, we see that these sets are indeed the Journé sets S_1 for $\widehat{\phi}_1$ and S_2 for $\widehat{\phi}_2$. $\square$

Remark 2. Neither $\text{Per } \phi_1$ nor $\text{Per } \phi_2$ is bounded away from 0 on its support, so that by [9], the translates of ϕ_1 and ϕ_2 do not even form a frame for their closed linear span V_0 . (This is true in the Cohen example as well.)

Figures 5 and 6 below show C^1 approximations to the graphs of $\widehat{\phi}_1$ and $\widehat{\phi}_2$ near the origin. As shown in Lemma 1, both functions have unbounded support, but the portions of these functions that do not appear in Figure 5 and Figure 6 have values less than .01 and .002 respectively. We will use $\widehat{\phi}_1$ and $\widehat{\phi}_2$ to define our C^∞ frame wavelet with C^∞ Fourier transform. To do this we will need the following properties of $\widehat{\phi}_1$ and $\widehat{\phi}_2$:

Proposition 2. The functions $\widehat{\phi}_1$ and $\widehat{\phi}_2$ defined in Proposition 1 are C^∞ .

Proof. We fix an a and show that $\widehat{\phi}_1$ and $\widehat{\phi}_2$ are C^∞ in a neighborhood of a . Because $h_{2,1}$ is 0 on $(-\frac{3}{7}, \frac{3}{7})$, all but a finite number of the lower triangular products of three successive factors described in Lemma 1 are in fact diagonal

Figure 5: A C^1 approximation to $\widehat{\phi}_1$

with single terms on the diagonal. Thus, each of the entries in the first column of the infinite product matrix is the sum of only a finite number of terms. Since $h_{1,1} = \sqrt{2}$ in a neighborhood of 0, each of the terms has only a finite number of factors not equal to 1. It will suffice to show that each of these finite products is C^∞ .

By construction, we have that the $h_{i,j}$ are all C^∞ everywhere except for $h_{1,1}$ at $n \pm \frac{2}{7}$, $h_{1,2}$ at $n \pm \frac{1}{7}$, and $h_{2,1}$ at $n \pm \frac{3}{7}$ for $n \in \mathbb{Z}$. We will show that whenever one of these discontinuities occurs as a factor in the infinite product, it is cancelled by a following factor that is 0 at the point of discontinuity. From the formula for the $t_{i,j}$ given in Lemma 1, we see that any term in the infinite product that contains a factor of $h_{2,1}(n \pm \frac{3}{7})$ must also contain a factor of one of the forms $h_{1,1}(n \pm \frac{2}{7})$, $h_{1,1}(n \pm \frac{3}{14})$, $h_{1,2}(n \pm \frac{3}{14})$, or $h_{1,2}(n \pm \frac{2}{7})$. The last three possibilities are 0 in a neighborhood of the point in question, so if we have a discontinuous factor of $h_{2,1}$, it is either cancelled out by a 0 factor, or we also have a factor of $h_{1,1}(n \pm \frac{2}{7})$ with a smaller n . Similarly, any term in the infinite product that contains a factor of $h_{1,1}(n \pm \frac{2}{7})$ must also contain a factor of one of the forms $h_{1,1}(n \pm \frac{5}{14})$, $h_{1,1}(n \pm \frac{1}{7})$, $h_{1,2}(n \pm \frac{5}{14})$, or $h_{1,2}(n \pm \frac{1}{7})$. The first three of these possibilities are 0 at the points in question, so any discontinuous factor of $h_{1,1}$ is either cancelled out by a 0 factor, or is followed by a factor of $h_{1,2}(n \pm \frac{1}{7})$ with an equal or smaller n . Finally, any term in the infinite product that contains a factor of $h_{1,2}(n \pm \frac{1}{7})$ must also contain a factor of either the form $h_{2,1}(n \pm \frac{1}{14})$ or the form $h_{2,1}(n \pm \frac{3}{7})$. The first of these possibilities is 0 at the point in question; the second possibility throws us back into the first type of discontinuity we considered above, but with a smaller n . We can repeat the above sequence of arguments if necessary, noting that each succeeding factor is evaluated at a point half the distance from the origin as its predecessor, so that

Figure 6: A C^1 approximation to $\hat{\phi}_2$

the chain above must eventually end with a factor of $h_{1,1}$ and thus with 0.

Thus each of the finite products that occur as terms in $\hat{\phi}_1$ and $\hat{\phi}_2$ has the form of product $f(x) = f_1(x)f_2(x)$ in a neighborhood of a , where $f_1(x)$ is C^∞ on $(a - \epsilon, a + \epsilon)$, with its value and all its derivatives, $f_1^{(n)}(a) = 0$, $n \geq 0$, and $f_2(x)$ is C^∞ on $(a - \epsilon, a) \cup (a, a + \epsilon)$, with a jump discontinuity at a , but with all derivatives satisfying $\lim_{x \rightarrow a^-} f_2^{(n)}(x) = \lim_{x \rightarrow a^+} f_2^{(n)}(x) = 0$, $n \geq 1$. Thus, f is C^∞ on $(a - \epsilon, a + \epsilon)$ with $f^{(n)}(a) = 0$, $n \geq 0$. $\square$

The next result shows that the $\hat{\phi}_i$ vanish rapidly at ∞ , to an extent determined by the integer r chosen at the beginning of the example.

Proposition 3. *The functions $\hat{\phi}_1$ and $\hat{\phi}_2$ defined in Proposition 1 satisfy $|x|^{r+1}\hat{\phi}_i(x) \rightarrow 0$ as $x \rightarrow \infty$.*

Proof. Using Lemma 1 we see that it will suffice to show that given an $\epsilon > 0$, there exists N such that $|x|^{r+1}|\hat{\phi}_i(x)| < \epsilon$ for $x \in A_n \cup B_n \cup C_n$ with $n > N$. Recall from that lemma that $x \in A_n \cup B_n \cup C_n$ has the form $x = d \left(\sum_{j=0}^n a_j 8^j + \pm r_0 \right)$, where $d \in 1, 2, 4$, $a_j = \pm 1$, and where $0 < r_0 < \frac{1}{7}$. For any such x , $\hat{\phi}_i(x)$ is the sum of less than 3^{n+1} terms of the form $\prod_{l=1}^\infty \frac{1}{\sqrt{2}} h_{i_l, j_l} \left(\frac{x}{2^l} \right)$, since once $x < \frac{6}{7}$, we have $h_{2,1}(x) = 0$, so that the triangular matrix described in Lemma 1 is actually diagonal with single term elements. To see how the argument of the h_{i_l, j_l} changes as we move from $\frac{x}{2^k}$ to $\frac{x}{2^{k+3}}$, we note that if y of the form $y = \sum_{j=0}^{n-k} a_{k+j} 8^j + a_{k-1} r_k$ with $\frac{1}{7} - \delta < r_0 < \frac{1}{7}$, then $\frac{y}{2} = 4 \left(\sum_{j=0}^{n-k-1} a_{k+j+1} 8^j + a_k r_{k+1} \right)$, $\frac{y}{4} = 2 \left(\sum_{j=0}^{n-k-1} a_{k+j+1} 8^j + a_k r_{k+1} \right)$, and $\frac{y}{8} = \sum_{j=0}^{n-k-1} a_{k+j+1} 8^j + a_k r_{k+1}$. The remainder terms, $d \cdot r_{k+1}$, take one of

two forms, depending on the value of a_{k-1} . If $a_{k-1} = +1$, then $4r_{k+1}$ is within $\frac{\delta}{2}$ of $\frac{4}{7}$, so that $\frac{1}{7} - \frac{\delta}{8} < r_{k+1} < \frac{1}{7}$, while if $a_{k-1} = -1$, $4r_{k+1}$ is within $\frac{\delta}{2}$ of $\frac{3}{7}$, so that $\frac{3}{14} < 2r_{k+1} < \frac{3}{14} + \frac{\delta}{4}$, and $\frac{1}{7} - \frac{1}{28} < r_{k+1} < \frac{1}{7}$. In the first case we will make use of the fact that as y decreases by a factor of $\frac{1}{8}$, δ decreases by a factor of $\frac{1}{8}$. In the second case we make use of the factor $h_{i,j}(z)$ with $\|z - \frac{3}{14}\| < \frac{\delta}{4}$, where $\|\cdot\|$ denotes the distance from the nearest integer. We note that in this second case, $h_{i,j}(z)$ is necessarily $h_{1,1}(z)$ since the other filters are 0 at such a z , and we were assuming that we were in the support of $\hat{\phi}_i(x)$. Thus, in the second case, we obtain a factor of $|p(z)|$ with $\|z - \frac{3}{14}\| < \frac{\delta}{4}$, and we reset δ to $\frac{1}{28}$. Since $x \in A_n \cup B_n \cup C_n$ satisfies $\frac{8^n}{2} < |x| < 8^{n+1}$, it will take between n and $n+1$ applications of this process of moving from y to $\frac{y}{8}$ to move into the unit interval. From this, if $a_j = 1$ for all j , we will obtain n factors of the form $p(z)$ for $\|z - \frac{3}{14}\| < \frac{1}{112}$. Thus, by applying the Mean Value Theorem to condition (5) in the definition of the function p , we see that we will have n factors $|h_{i,j}(\frac{x}{2^r})|$ each of which is less than $(\frac{1}{112})^{r+2}$. Each time $a_j = +1$, we will decrease the value of δ by a factor of $\frac{1}{8}$ instead of obtaining a new small factor. If $a_j = +1$ for all j , we will eventually arrive at $h_{1,1}(z)$ for $|z - \frac{1}{7}| < \frac{1}{8^n}$. Again, by applying the Mean Value Theorem to condition (5) in the definition of p , we see that this gives us a factor of $|h_{i,j}(\frac{x}{2^r})|$ which is less than $(\frac{1}{8^n})^{r+2}$. Values of $x \in A_n \cup B_n \cup C_n$ with a mixture of $a_j = +1$ and $a_j = -1$ will be somewhere between these two extremes, but all will have one or more factors of $p(x)$ among the $|h_{i,j}(\frac{x}{2^r})|$ with x so close to $\frac{3}{14}$ or $\frac{1}{7}$ that the product of these factors is less than $(\frac{1}{8^n})^{r+2}$. Since the other factors are bounded by 1, we thus get that each term in $\hat{\phi}_i(x)$ is bounded in absolute value by $\frac{1}{\sqrt{2}} 3^n (\frac{1}{8^n})^{r+2}$. Thus, for $x \in A_n \cup B_n \cup C_n$, we have $|\hat{\phi}_i(x)| < \frac{3^{n+1}}{(\sqrt{2})^{3n} 8^{n(r+2)}}$. Finally, for such x , $|x^{r+1} \hat{\phi}_i(x)| < \frac{3^{n+1} 8^{(n+1)(r+1)}}{8^{n(r+2)+\frac{r}{2}}} = \frac{3^{n+1} 8^{r+1}}{8^{\frac{3n}{2}}} \rightarrow 0$ as $n \rightarrow \infty$. $\square$

We are now ready to prove our main theorem:

Theorem 4. *For any fixed integer $r \geq 0$, there exists a real-valued normalized tight frame wavelet ψ such that $\psi \in C^r$, $\psi \in C^\infty$ and such that the multiplicity function associated to ψ is that of the Journé wavelet.*

Proof. We build ψ using the technique described in Theorem 3, with low-pass filter functions $h_{i,j}$ defined in equations (13)–(16), and with high-pass filters given by

$$g_1(x) = \begin{cases} e^{2\pi i x} \overline{p(x + \frac{1}{2})} & x \in [-\frac{2}{7}, \frac{2}{7}) \\ 0 & \text{otherwise} \end{cases}$$

$$g_2(x) = \begin{cases} -e^{2\pi i x} \overline{p(x)} & x \in [-\frac{1}{7}, \frac{1}{7}) \\ 0 & \text{otherwise} \end{cases}$$

It is easily checked that these generalized high-pass filter functions satisfy the filter equations (11) and (12). In fact, as their form suggests, they were built

from the generalized low-pass filters using the classical high-pass filter obtained from p via equation (7). The frame wavelet ψ is defined as in Theorem 3, by $\widehat{\psi}(x) \equiv \frac{1}{\sqrt{2}} \left(g_1(\frac{x}{2})\widehat{\phi}_1(\frac{x}{2}) + g_2(\frac{x}{2})\widehat{\phi}_2(\frac{x}{2}) \right)$, where $\widehat{\phi}_1$ and $\widehat{\phi}_2$ are the functions built from the $\{h_{i,j}\}$ in Proposition 1. The wavelet ψ is real-valued since the fact that both the low and high pass filters are symmetric forces $\widehat{\psi}$ to be symmetric as well. We have that $\widehat{\psi}$ is C^∞ since Lemma 2 established that $\widehat{\phi}_1$ and $\widehat{\phi}_2$ are C^∞ , and g_1 and g_2 are as well. Further, we have that $|x|^{r+1}\widehat{\psi}(x) \rightarrow 0$ as $x \rightarrow \infty$, since $\widehat{\phi}_1$ and $\widehat{\phi}_2$ were shown to have this property in Proposition 3 and g_1 and g_2 are bounded by $\sqrt{2}$. Thus the wavelet ψ itself satisfies $\psi \in C^r$.

It remains to show that ψ determines the same GMRA as ϕ_1 and ϕ_2 , so that this wavelet also has the multiplicity function of Journé. It was shown in [5] that $\psi \in V_1$, where $\{V_j\}$ is the GMRA determined by ϕ_1 and ϕ_2 as in Proposition 1. This says that ψ is *obtained from* the GMRA in the sense defined by Zalik [26]. We will now show that in this particular case, ψ is *associated with* the GRMA $\{V_j\}$ in the sense that V_j is the closed linear span of $\{\psi_{l,k}\}_{l < j}$. (For more on this distinction, see e.g. [10].) Since we already know (by $\psi \in V_1$) that V_j contains this closed linear span, it will suffice to show that $\widehat{V}_0$ is contained in the closure of the span of $\{\widehat{\psi}_{l,k}\}_{l < 0}$.

We will do this by defining a bounded surjective linear map $T : L^2(S_1) \oplus L^2(S_2) \mapsto \widehat{V}_0$, that takes a tight frame for $L^2(S_1) \oplus L^2(S_2)$ to $\{\widehat{\psi}_{l,k}\}_{l < 0}$. We define $T(f_1, f_2) = f_1\widehat{\phi}_1 + f_2\widehat{\phi}_2$, where $f_i \in L^2(S_i)$ is extended to a periodic function. T maps onto $\widehat{V}_0$ since by Lemma 1, the support of $\widehat{\phi}_i$ is the periodization of S_i . To see that T is bounded, we compute the norm

$$\begin{aligned} \|T(\{f_i\})\|^2 &= \int_{\mathbb{R}} \left| f_1(x)\widehat{\phi}_1(x) + f_2(x)\widehat{\phi}_2(x) \right|^2 dx \\ &= \int_{\mathbb{R}} \left| f_1(x)\widehat{\phi}_1(x) \right|^2 + \left| f_2(x)\widehat{\phi}_2(x) \right|^2 dx \\ &= \sum_{j \in \mathbb{Z}} \int_{\mathbb{T}} \left| f_1(x)\widehat{\phi}_1(x+j) \right|^2 + \left| f_2(x)\widehat{\phi}_2(x+j) \right|^2 dx \\ &= \int_{\mathbb{T}} |f_1(x)|^2 \sum_{j \in \mathbb{Z}} \left| \widehat{\phi}_1(x+j) \right|^2 + |f_2(x)|^2 \sum_{j \in \mathbb{Z}} \left| \widehat{\phi}_2(x+j) \right|^2 dx, \end{aligned}$$

where the second equality follows from the disjointness of the supports of $\widehat{\phi}_1$ and $\widehat{\phi}_2$. Let $\text{Per } \phi_i(x) \equiv \sum_{j \in \mathbb{Z}} \left| \widehat{\phi}_i(x+j) \right|^2$. To show that T is bounded, it will suffice to show that $\text{Per } \phi_i$ is bounded on $\mathbb{T}$ for $i = 1, 2$. This follows from

Lemma 1 by writing, for $x \in [-\frac{1}{2}, \frac{1}{2}]$,

$$\begin{aligned} \text{Per } \phi_i(x) &= \sum_{n=0}^{\infty} \sum_{\{a_j\} \in \{-1,1\}^n} \widehat{\phi}_i(x + \sum_{j=0}^n a_j 8^j) \\ &\leq \sum_{n=0}^{\infty} 2^n \frac{1}{8^{(n-1)r}} \end{aligned}$$

where the last step follows from Proposition 3.

Now to see that T takes a tight frame for $L^2(S_1) \oplus L^2(S_2)$ to $\{\widehat{\psi}_{l,k}\}_{l < 0}$, we adopt some notation from [5]. Define the operator $S_G : L^2(\mathbb{T}) \rightarrow L^2(S_1) \oplus L^2(S_2)$ by

$$[S_G(f)](x) = \{g_1(x)f(2x), g_2(x)f(2x)\}$$

and $S_H : L^2(S_1) \oplus L^2(S_2) \rightarrow L^2(S_1) \oplus L^2(S_2)$ by

$$[S_H(\{f_1, f_2\})](x) = \{h_{1,1}(x)f_1(2x) + h_{2,1}(x)f_2(2x), h_{1,2}(x)f_1(2x)\}.$$

It is shown in [5] (Lemma 3.3) that $\{S_H^n(S_G(e^{2\pi i k x}))\}_{k \in \mathbb{Z}, n=0,1,2,\dots}$ forms a normalized tight frame for $L^2(S_1) \oplus L^2(S_2)$. We complete the proof by showing that the operator T takes this frame to $\{\widehat{\psi}_{l,k}\}_{l < 0}$. Note first that for $n = 0$, we have

$$\begin{aligned} T(S_G(e^{2\pi i k x})) &= g_1(x)e^{4\pi i k x}\widehat{\phi}_1(x) + g_2(x)e^{4\pi i k x}\widehat{\phi}_2(x) \\ &= e^{4\pi i k x}\widehat{\psi}(2x) \\ &= \widehat{\psi}_{-1,k} \end{aligned}$$

Thus the result will follow from the fact that T intertwines the operators S_H on $L^2(S_1) \oplus L^2(S_2)$ and inverse dilation δ^{-1} on $\widehat{V}_0$:

$$\begin{aligned} [T(S_H(\{f_1, f_2\}))](x) &= h_{1,1}(x)f_1(2x) + h_{2,1}(x)f_2(2x)\widehat{\phi}_1(x) + h_{1,2}(x)f_1(2x)\widehat{\phi}_2(x) \\ &= f_1(2x) \left(h_{1,1}(x)\widehat{\phi}_1(x) + h_{1,2}(x)\widehat{\phi}_2(x) \right) + f_2(2x)h_{2,1}(x)\widehat{\phi}_1(x) \\ &= f_1(2x)\sqrt{2}\widehat{\phi}_1(2x) + f_2(2x)\sqrt{2}\widehat{\phi}_2(2x) \\ &= \left[\delta^{-1} \left(f_1\widehat{\phi}_1 + f_2\widehat{\phi}_2 \right) \right](x) \\ &= [\delta^{-1}(T(f))](x). \end{aligned}$$

□

Remark 3. While the dilates and translates of the wavelet ψ defined in Theorem 4 do form a normalized tight frame for all of $L^2(\mathbb{R})$, the translates of ψ do not even form a frame for their linear span. We can see this using the result in [9] once again, since $\text{Per } \psi(x) \equiv \sum_{j \in \mathbb{Z}} \left| \widehat{\psi}(x + j) \right|^2$ is not bounded away from 0 on its support. In particular, $\text{Per } \psi$ is continuous, yet nonzero on $\pm(\frac{2}{7}, \frac{4}{7})$, and 0 on $\pm(\frac{4}{7}, \frac{6}{7})$.
